

Analysis of algorithms

The theoretical study of computer-program performance and resource usage.

What's more important than performance?

- modularity
- correctness
- maintainability
- functionality
- robustness

- user-friendliness
- programmer time
- simplicity
- extensibility
- reliability

Why study algorithms and performance?

- Algorithms help us to understand scalability.
- Performance often draws the line between what is feasible and what is impossible.
- Algorithmic mathematics provides a *language* for talking about program behavior.
- Performance is the *currency* of computing.
- The lessons of program performance generalize to other computing resources.
- Speed is fun!

The problem of sorting

Input: sequence $\langle a_1, a_2, ..., a_n \rangle$ of numbers.

Output: permutation $\langle a'_1, a'_2, ..., a'_n \rangle$ such that $a'_1 \le a'_2 \le \cdots \le a'_n$.

Example:

Input: 8 2 4 9 3 6

Output: 2 3 4 6 8 9

Insertion sort

"pseudocode"

```
Insertion-Sort (A, n) \triangleright A[1 ... n]

for j \leftarrow 2 to n

do key \leftarrow A[j]

i \leftarrow j - 1

while i > 0 and A[i] > key

do A[i+1] \leftarrow A[i]

i \leftarrow i - 1

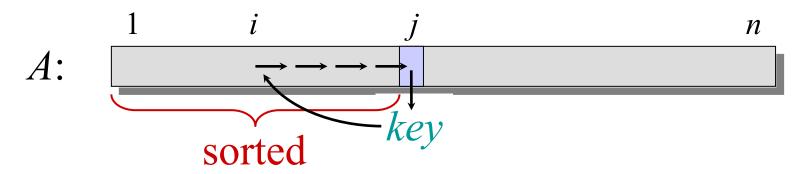

A[i+1] = key
```

Insertion sort

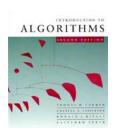

"pseudocode"

INSERTION-SORT (A, n) \triangleright A[1 ... n]for $j \leftarrow 2$ to ndo $key \leftarrow A[j]$ $i \leftarrow j - 1$ while i > 0 and A[i] > keydo $A[i+1] \leftarrow A[i]$ $i \leftarrow i - 1$ A[i+1] = key

Running time

- The running time depends on the input: an already sorted sequence is easier to sort.
- Parameterize the running time by the size of the input, since short sequences are easier to sort than long ones.
- Generally, we seek upper bounds on the running time, because everybody likes a guarantee.

Kinds of analyses

Worst-case: (usually)

• T(n) = maximum time of algorithm on any input of size n.

Average-case: (sometimes)

- T(n) = expected time of algorithm over all inputs of size n.
- Need assumption of statistical distribution of inputs.

Best-case: (bogus)

• Cheat with a slow algorithm that works fast on *some* input.

Machine-independent time

What is insertion sort's worst-case time?

- It depends on the speed of our computer:
 - relative speed (on the same machine),
 - absolute speed (on different machines).

BIG IDEA:

- Ignore machine-dependent constants.
- Look at *growth* of T(n) as $n \to \infty$.

"Asymptotic Analysis"

Θ-notation

Math:

```
\Theta(g(n)) = \{ f(n) : \text{there exist positive constants } c_1, c_2, \text{ and} 

n_0 \text{ such that } 0 \le c_1 g(n) \le f(n) \le c_2 g(n) 

for all n \ge n_0 \}
```

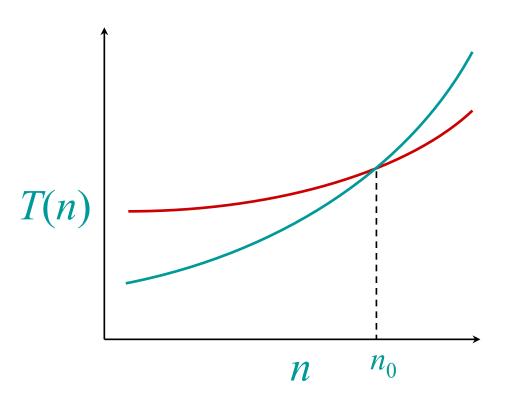

Engineering:

- Drop low-order terms; ignore leading constants.
- Example: $3n^3 + 90n^2 5n + 6046 = \Theta(n^3)$

Asymptotic performance

When *n* gets large enough, a $\Theta(n^2)$ algorithm *always* beats a $\Theta(n^3)$ algorithm.

- We shouldn't ignore asymptotically slower algorithms, however.
- Real-world design situations often call for a careful balancing of engineering objectives.
- Asymptotic analysis is a useful tool to help to structure our thinking.

Insertion sort analysis

Worst case: Input reverse sorted.

$$T(n) = \sum_{j=2}^{n} \Theta(j) = \Theta(n^2)$$
 [arithmetic series]

Average case: All permutations equally likely.

$$T(n) = \sum_{j=2}^{n} \Theta(j/2) = \Theta(n^2)$$

Is insertion sort a fast sorting algorithm?

- Moderately so, for small *n*.
- Not at all, for large *n*.

Merge sort

MERGE-SORT $A[1 \dots n]$

- 1. If n = 1, done.
- 2. Recursively sort $A[1..\lceil n/2\rceil]$ and $A[\lceil n/2\rceil+1..n]$.
- 3. "Merge" the 2 sorted lists.

Key subroutine: MERGE

20 12

13 11

7 9

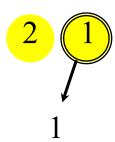

2 1

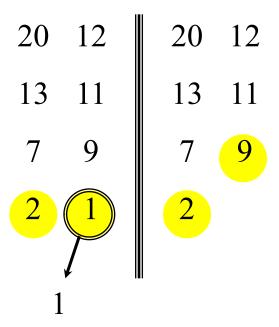

20 12

13 11

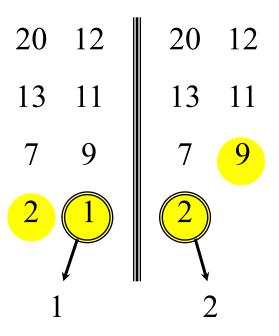

7 9

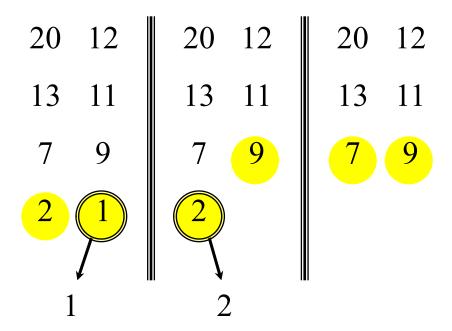

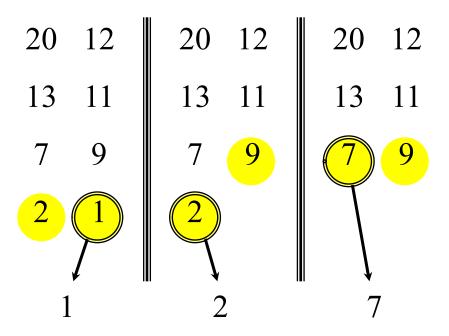

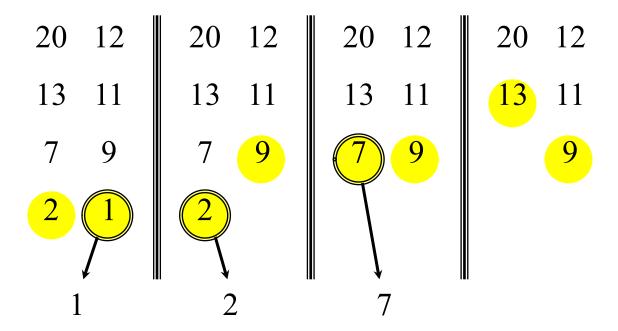

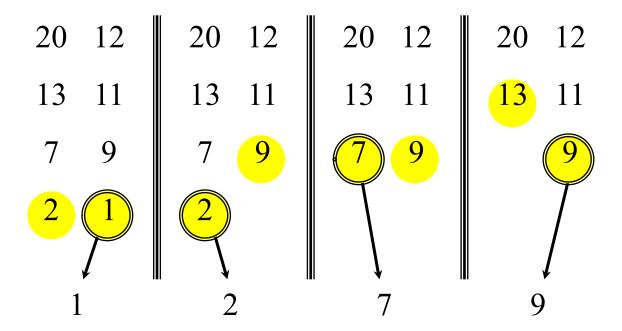

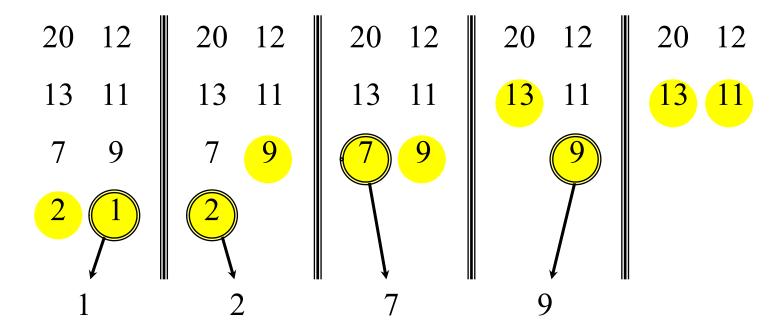

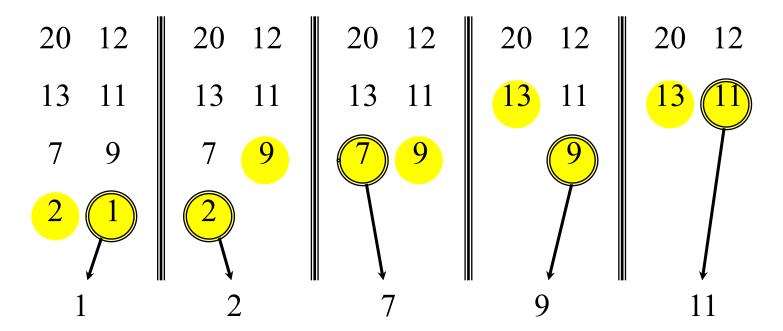

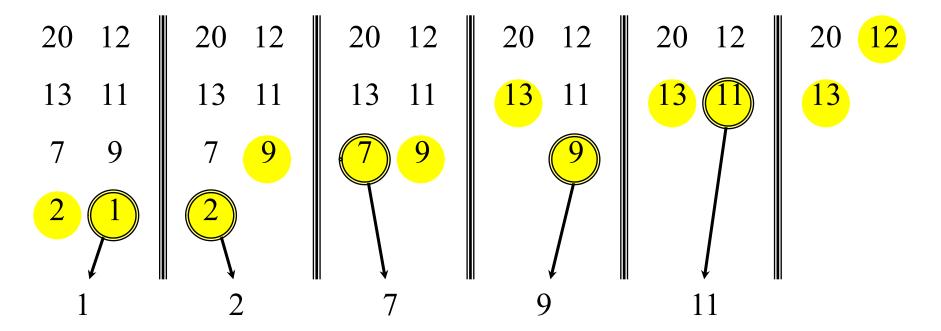

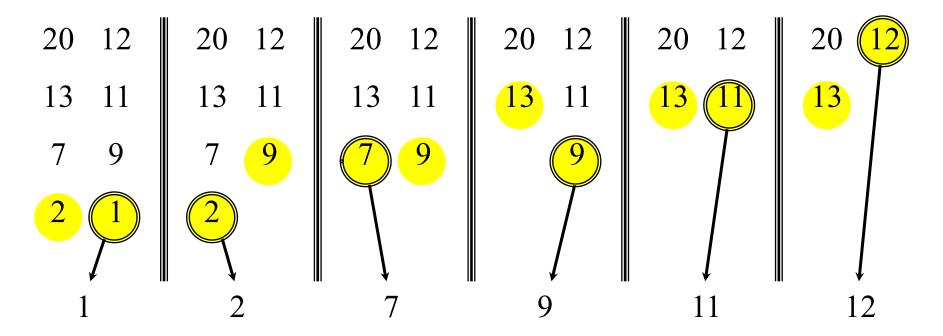

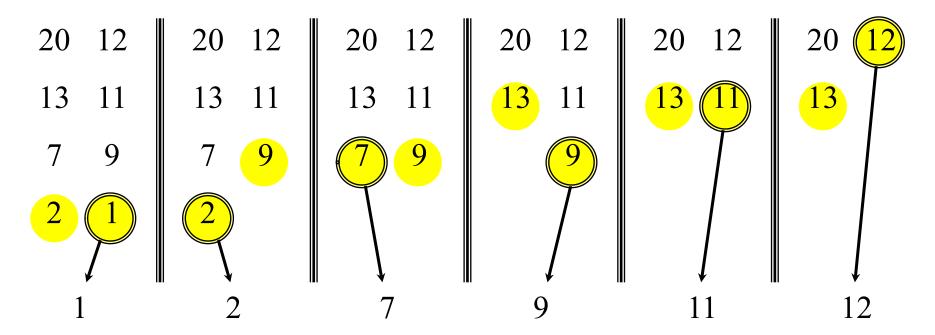

Time = $\Theta(n)$ to merge a total of n elements (linear time).

Analyzing merge sort

```
\Theta(1)
2T(n/2)
Abuse
\Theta(n)
1. If n = 1, done.

2. Recursively sort A[1 ... \lceil n/2 \rceil]
and A[\lceil n/2 \rceil + 1 ... n].

3. "Merge" the 2 sorted lists
```

Merge-Sort A[1 ... n]

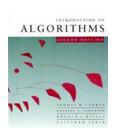

Sloppiness: Should be $T(\lceil n/2 \rceil) + T(\lfloor n/2 \rfloor)$, but it turns out not to matter asymptotically.

Recurrence for merge sort

$$T(n) = \begin{cases} \Theta(1) \text{ if } n = 1; \\ 2T(n/2) + \Theta(n) \text{ if } n > 1. \end{cases}$$

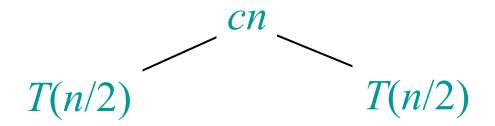

- We shall usually omit stating the base case when $T(n) = \Theta(1)$ for sufficiently small n, but only when it has no effect on the asymptotic solution to the recurrence.
- CLRS and Lecture 2 provide several ways to find a good upper bound on T(n).

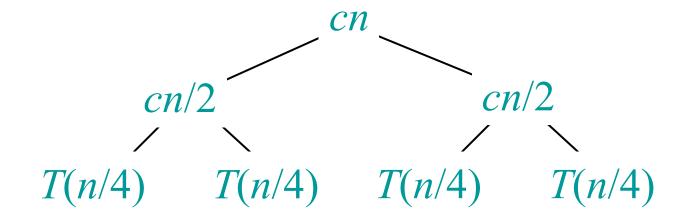

Solve
$$T(n) = 2T(n/2) + cn$$
, where $c > 0$ is constant.
$$T(n)$$

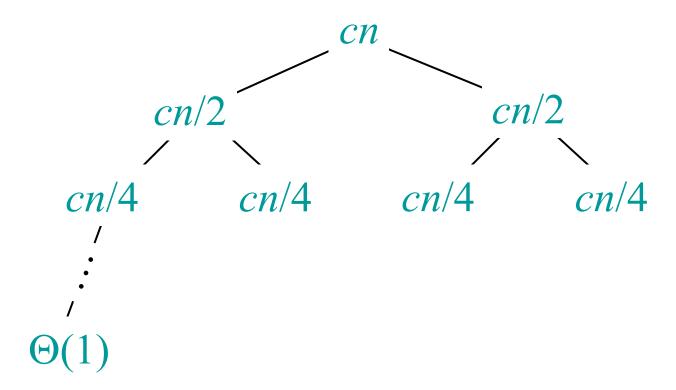

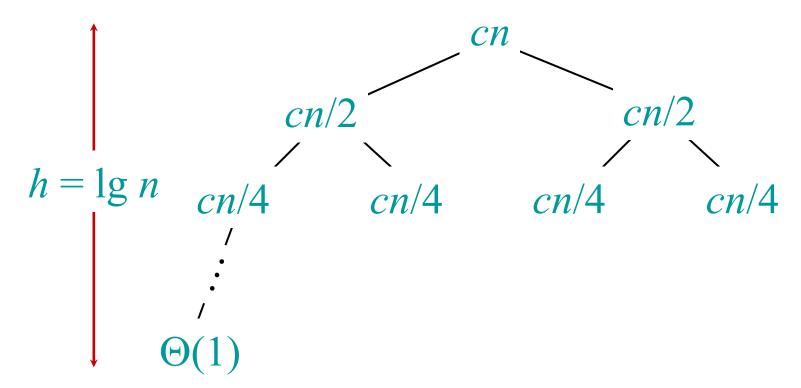

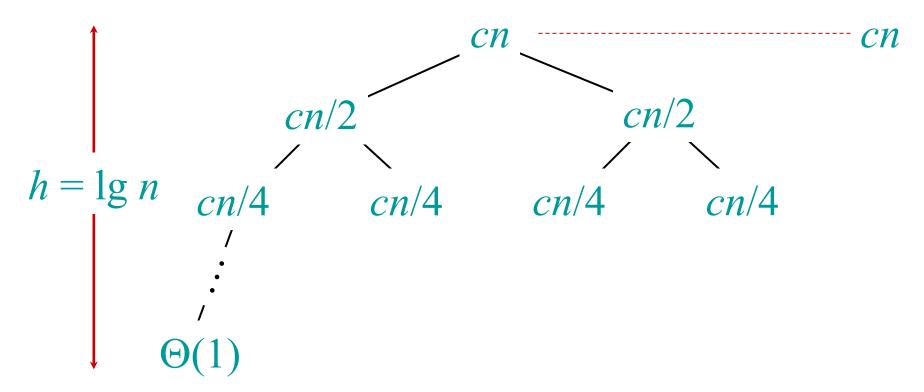

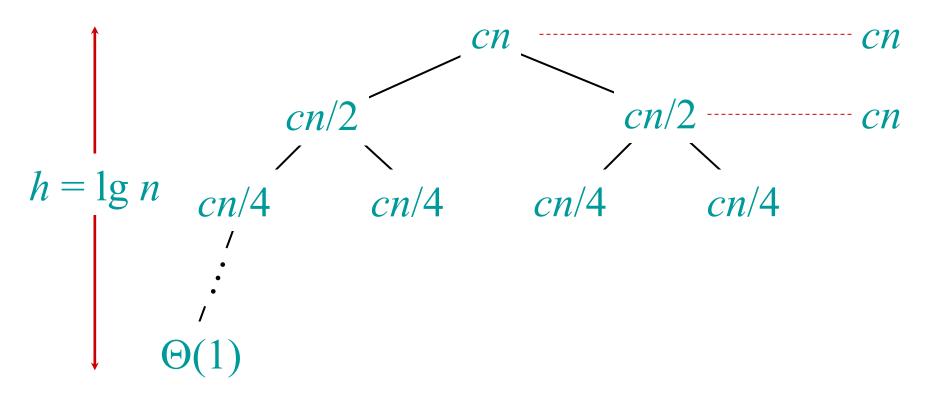

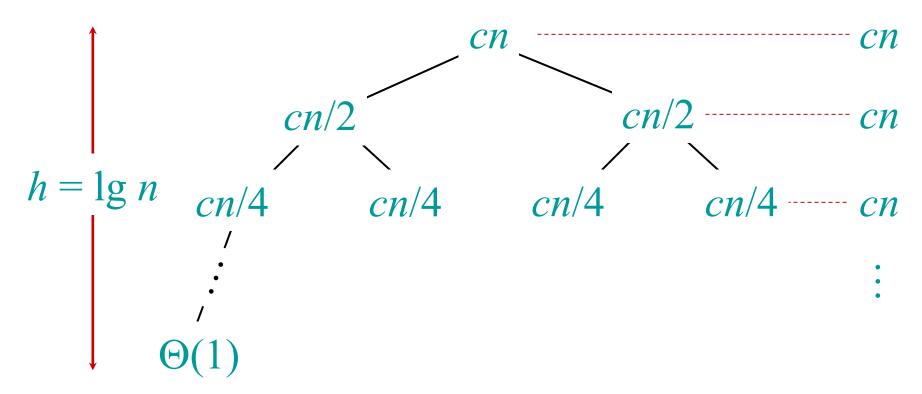

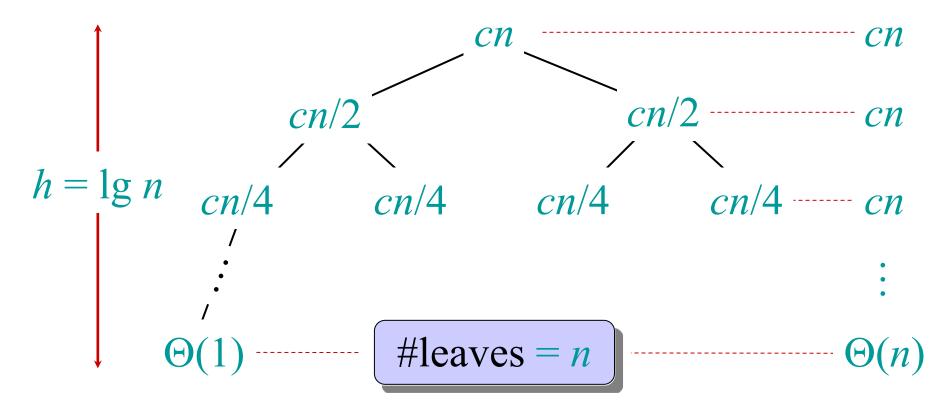

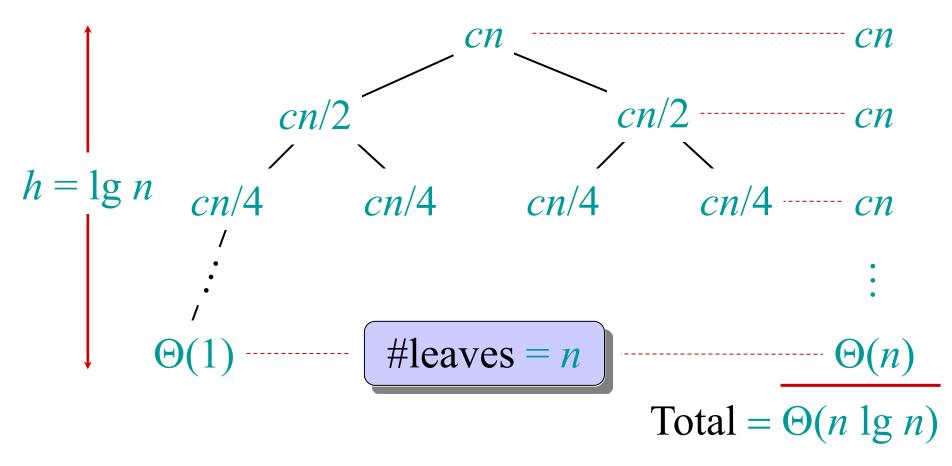

Conclusions

- $\Theta(n \lg n)$ grows more slowly than $\Theta(n^2)$.
- Therefore, merge sort asymptotically beats insertion sort in the worst case.
- In practice, merge sort beats insertion sort for n > 30 or so.
- Go test it out for yourself!
